Activity

Skiing

Up on the shoulder of Blackmore today. HS 125cm plus or minus, with 15-20cm HST. Poor structure is widespread. No cracking/collapsing/signs of avalanche activity on basal layers. The steep, wind loaded terrain on lookers R of the N Face (NE aspect) slid naturally some time towards the end of the snow event on the interface, around 30 cm estimated depth, some crowns up to 40m across. Nothing ran more than 100m. SS-N-D1R2-I. On the east face, nothing more than size 1 Dry Loose. This round of snow didn't seem to tip the scales around the general Blackmore area but I'm not really trusting larger pieces of terrain in the Hyalite region for the foreseeable future.
